BEST AVAILABLE IMAGES

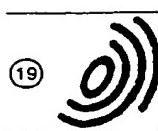

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- BLACK BORDERS**
- IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- FADED TEXT OR DRAWING**
- BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- SKEWED/SLANTED IMAGES**
- COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- GRAY SCALE DOCUMENTS**
- LINES OR MARKS ON ORIGINAL DOCUMENT**
- REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.

(54) Scanning device.

(57) A scanning device for scanning an original which is set at a predetermined position and has information recorded thereon comprises : a plurality of light emission members for emitting lights of different wavelengths from each other ; a first reflection member having a plurality of reflection planes for selectively reflecting the lights of a plurality of wavelengths directed by the light emission members and light emission auxiliary means ; second reflection member for reflecting the light reflected by the first reflection member to focus it on original sheet in a linear pattern ; and focusing means for focusing the information of the original onto a sensor in accordance with the reflected light from the second reflection member.

The device has depressions arranged around the light emission members for reflecting lights and the depressions are shaped differently depending on the wavelengths of the light emissions of the corresponding light emission members so that the light intensities of the

respective wavelengths of light emissions and the decrease of ununiformity of the light intensity are attained.

embodiment of the present invention; Figs. 2A and 2B show detail of a light source 601 in Fig. 1; and Fig. 3 shows a line arrangement of LED chips and a light emission member 301 of the LED chip and depressions 302 and 303.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Fig. 1 shows a device for forming an image in one embodiment of the present invention.

In Fig. 1, the device comprises a light source 601, a concave mirror 611, a mirror 620, a mirror 621, an image forming lens 631 and a sensor 641.

The light source 601 uses LED chips of three colors as a light emission source.

The convex mirror 611 is of tridental design, that is, it is a mirror having curvatures of two different axes for linearly focusing the light from the light source 601 onto a plane of a film 622.

The mirror 620 reflects the light reflected by the concave mirror 611 to direct it to the plane of the film 622.

The mirror 621 reflects the light transmitted through the film 622 to the image forming lens 631.

The image forming lens 631 focuses the reflected light from the mirror 621 onto a sensor 641.

The sensor 641 is a CCD which converts the light focused by the image forming lens 631 to an electrical signal.

The film 622 may be a negative film or a positive film so that is light transparency.

Figs. 2A and 2B show detail of the light source 601 of Fig. 1.

In Figs. 2A and 2B, the light source 601 comprises two red LED chips, four green LED chips, six blue LED chips, a support table 650, a dichroic mirror 660, an infrared block filter 661, a common lead 670, a blue lead 671, a red-green lead 672 and an insulator 680.

The red LED chip uses GaAlAs (gallium aluminum arsenide) as a material and has a cathode electrode on a top light emission plane and an anode electrode on a bottom surface. The green LED chip uses GaP/GaP (gallium phosphor/gallium phosphor) as a material and has an anode electrode on a top light emission plane and a cathode electrode on a bottom plane. The blue LED chip use SiC (silicon carbide) as a material and has an anode electrode on a top light emission plane and a cathode electrode on a bottom plane. They generate lights of red, green and blue, respectively.

Six LED chips are arranged on the support table 650 in two lines, namely, the red LED chips and the green LED chips in one line and the blue LED chips in one line. In the line of the red and green LED chips, they are arranged in the order of green, red, green, green, red and green. They are arranged by taking

the ununiformity of illumination due to the difference in numbers into consideration, although the present invention is not limited thereto and further improvement may be attained by changing the distances between the LED chips.

The numbers of LED chips of different colors used are different because of a big difference between light emission intensities per chip of the presently available LED chips of various colors. However, since the illumination light intensity may not be unified by merely changing the numbers of chips, the light emission times of the LED chips of the respective colors may be adjusted when the image is read.

The respective LED chips are arranged such that the optical distances from the light emission surfaces of the respective LED chips to the exit planes are equal. As a result, the light of all colors are focused on the film 622.

The support table 650 is made of a conductive material.

The common lead 670 is electrically connected to the support table 650 and the blue lead 671 and the red/blue lead 672 are insulated from the support table 650.

The common lead 670 is connected to the anodes of the red LED chips, the cathodes of the green LED chips and the cathodes of the blue LED chips through the support table 650.

The blue lead 671 is insulated from the support table 650 by an insulator 680, and wire-bonded to the anodes of the blue LED chips.

The red/green lead 672 is insulated from the support table by the insulator 680 and wire-bonded to the cathodes of the red LED chips and the anodes of the green LED chips.

It is necessary to arrange the red LED chips and the green LED chips which use the common lead, in the opposite polarities so that the red, green and blue LED chips can independently emit lights. Since the red LED chip and the green LED chip used in the present embodiment are of opposite polarities as described above, it may be attained by a vertical arrangement for all LED chips.

The dichroic mirror 660 comprises a dichroic plane 666 and an aluminum plane 667 coated by an aluminum layer. The blue light emitted from the blue LED chip is reflected by the dichroic plane 666, and the red and green lights emitted from the red and green LED chips pass through the dichroic plane 666 and are reflected by the aluminum plane 667. Those reflected lights pass through the same light pass on an exit plane.

The blue LED chip which use SiC as the material emits not only the blue light but also a small quantity of green light. Since a blue reflection film for selectively reflecting only the blue light is applied to the dichroic plane 666 of the dichroic mirror 660, the green light from the aluminum plane 667 is not reflected.

slightly closer to the dichroic mirror 660 in order to defocus the light in the present embodiment, it may be arranged to be further to obtain the defocusing. However, they are arranged to be closer in order to prevent the light intensity from being reduced.

Since the light intensity decreases when the light is defocused, the positions of the LED chips which have high illumination light intensity may be shifted. In the present embodiment, the red LED chips correspond to such LED chips.

In the above embodiments, the light is transmitted through the recording medium such as the film. Alternatively, the present invention is applicable to a device which reflects the information of the recording medium to read it.

Since the optical aid means is provided in the present invention, the light from the light emission member can efficiently directed.

Since the optical distances from the light emission members to the recording medium are equal, the light intensity on the recording member increases.

Since the light is focused slightly off the recording medium, the positioning of the sensor is facilitated and the ununiformity of the light intensity of the light illuminating the recording medium is eliminated.

By converging the light by the lens aperture, the flare is prevented and a light image of a high contrast is attained.

Since the reflective depressions which are different depending on the wavelength of the light emission are provided, the light intensities are increased and the ununiformity of the light intensity is reduced for the respective wavelengths of light emission.

Since the first reflection member reflects only the visible light or a light of only a desired wavelength, no adverse affect to the information is produced and the infrared ray is not reflected.

In the embodiment, since the LED chips are arranged so that they are inclined approximately 30 degrees to arrange the four corners around the center axis in order to bring the maximum light emission portion of the light emission member around the center axis of the light emission member, the light intensity on the center axis of the line increases.

Since the focusing means for focusing the reflected light from the first reflection member to the second reflection member is provided, the leakage of the reflected light is prevented.

Claims

1. A scanning device for scanning an original set at a predetermined position and having information recorded thereon comprising:
a plurality of light emission members for emitting lights of different wavelengths from each other;

optical aid means arranged around said light emission member for focusing lights of different wavelengths emitted by said light emission members;

said optical aid means being depressions capable of reflecting lights and having different shapes depending on the wavelengths or distribution of the light emissions of the corresponding light emission members;

a first reflection member having a plurality of reflection planes for selectively reflecting the lights of a plurality of wavelengths directed by said light emission members and said optical aid means;

a second reflection member for reflecting the light reflected by the first reflection member to focus the light on the original in a linear pattern; and

focusing means for focusing the information of the original onto a sensor in accordance with the reflected light from said second reflection member.

- 25 2. A scanning device according to Claim 1 wherein said light emission members are arranged such that optical distances from the document sheet are equal.

30 3. A scanning device for scanning an original set at a predetermined position and having information recorded thereon comprising:
 a plurality of light emission members for emitting lights of different wavelengths from each other;

35 optical distances from said light emission members to the original varying from wavelength to wavelength of the light emissions of said light emission members;

40 a first reflection member having a plurality of reflection planes for selectively reflecting the lights of a plurality of wavelengths emitted by said light emission members;

45 a second reflection member for reflecting the light reflected by the first reflection member to focus the light on the original in a linear pattern; and

50 focusing means for focusing the information of original onto a sensor in accordance with the reflected light from said second reflection member.

55 4. A scanning device for scanning an original set at a predetermined position and having information recorded thereon comprising:
 a plurality of light emission members for emitting lights of different wavelengths from each other;

lights of a plurality of wavelengths emitted by said light emission members;

a second reflection member for reflecting the light reflected by the first reflection member to focus the light on the original in a linear pattern; directing means for directing reflected light from said first reflection means to said second reflection means; and

focusing means for focusing the information of the original onto a sensor in accordance with the reflected light from said second reflection member;

the information light of the original projected by said second reflection means being converged smaller than an aperture of said lens.

11. A light projection device for a scanning device for scanning an original having information recorded thereon comprising:

a plurality of light emission members for emitting lights of different wavelengths from each other;

said light emission members being arranged in line and arranged such that a maximum light intensity portion appears around a center axis of the line; and

optical aid means arranged around said light emission members for focusing the lights of different wavelengths emitted by said light emission members;

said optical aid means having different shapes depending on the wavelengths of the light emissions of the corresponding light emission members.

12. A light projection device according to Claim 11 wherein said light emission members are LED's having light emission portions of generally square shape and said LED's are arranged such that one side of the square is inclined approximately 30 degrees from the axis of the line.

13. A light source for use in a scanning device, said light source comprising an array of light-emitting elements arranged to emit light at a plurality of wavelengths, each element being provided with a respective reflector, the reflectors having different configurations, and the intensity distribution of the light emitted by said source being dependent on those configurations.

14. A scanning device for scanning an original located at a predetermined position with an array of light-emitting elements arranged to emit light at a plurality of wavelengths, the optical distances between the elements and the predetermined position varying, and the intensity distribution of the light incident in the original being dependent on

the variations in those distances.

15. A scanning device for scanning an original located at a predetermined position, said device comprising means for focusing an incident light beam at a focus point slightly offset from said predetermined position.

16. A scanning device for scanning an original, the device comprising a lens for focusing light from said original on to a detector and means for causing the light entering said lens to be converged to a size smaller than the aperture of said lens.

17. A scanning device for scanning an original, said device comprising means for reflecting incident light on to said original, said reflecting means being arranged to reflect substantially only visible light.

18. A scanning device for scanning an original, said device comprising means for reflecting incident light on to said original and means for detecting the light after incidence, said reflecting means being arranged to reflect substantially only light having a wavelength appropriate to the response characteristics of said detecting means.

19. A light source for use in a scanning device, said light source comprising an array of light-emitting elements arranged in a substantially straight line, each having a generally square light-emitting face, each element being oriented such that the corners of the respective faces are close to said line.
